

API Automation Testing Report – Create New Post using Rest Assured

Objective

The objective of this assignment was to automate the creation of a new post using Rest Assured by sending a POST request to the JSONPlaceholder API and validating the response.

Technology Stack

- Language: Java
- Build Tool: Maven
- API Automation Library: Rest Assured
- Test Framework: JUnit 5
- JSON Serializer: Jackson Databind
- IDE: IntelliJ IDEA

API Details

Base URL

<https://jsonplaceholder.typicode.com>

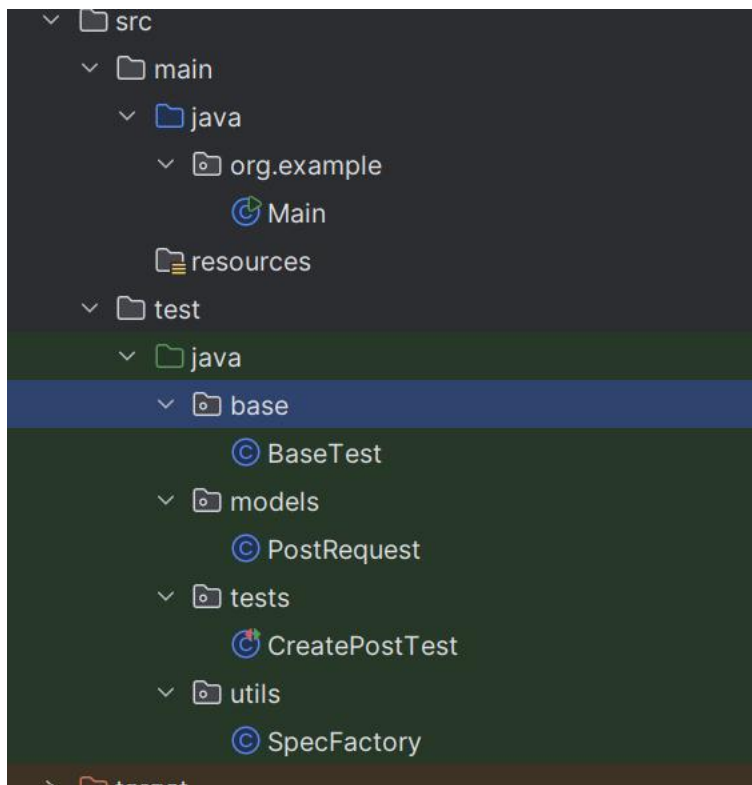

Endpoint

POST /posts

Request Body

```
{  
  "title": "Automation Testing",  
  "body": "Rest Assured Assignment",  
  "userId": 1  
}
```

Project Structure

Implementation Details

1. BaseTest

- Configured the Base URI for the API.
- Used `@BeforeAll` to initialize the common API configuration before test execution.

2. PostRequest POJO

Created a Java POJO containing:

- title
- body
- userId

The POJO was automatically converted into JSON using the Jackson Databind library during request execution.

3. SpecFactory

Created a reusable Request Specification containing:

- Content-Type: application/json

Although the current assignment contains only one API request, using a Request Specification demonstrates good framework design and allows common configurations such as headers, authentication, and content type to be reused across multiple API tests.

4. CreatePostTest

The test performs the following actions:

- Creates the request body using the PostRequest POJO.
 - Sends a POST request to /posts.
 - Stores the response.
 - Validates the response status code.
 - Verifies the response body fields using JUnit assertions.
-

Validations Performed

Status Code Validation

Verified that the API returned:

201 Created

Response Body Validation

Validated the following response fields:

- title
- body
- userId
- id

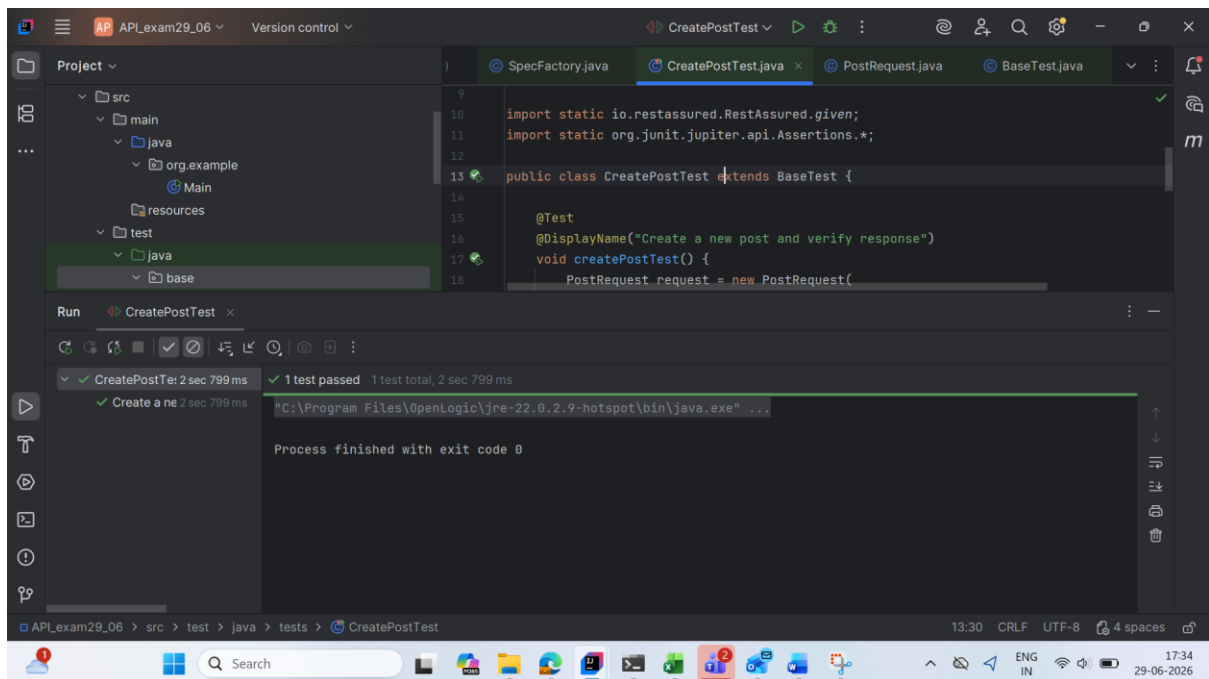

Assertions performed:

- Title equals "Automation Testing"
- Body equals "Rest Assured Assignment"

- User ID equals 1
- ID is generated and is not null

Test Result

- POST request executed successfully.
- Response status code validated successfully.
- Response body validated successfully.
- All assertions passed.
- Test execution completed without failures

Conclusion

The assignment was successfully completed by automating a POST API request to the JSONPlaceholder service. The framework followed a structured approach using BaseTest, POJO models, Request Specifications, and JUnit assertions. The API response was validated against the expected status code and response fields, demonstrating a clean and maintainable API automation solution.
