

REST ASSURED API TESTING

NAME: BHUMIKA

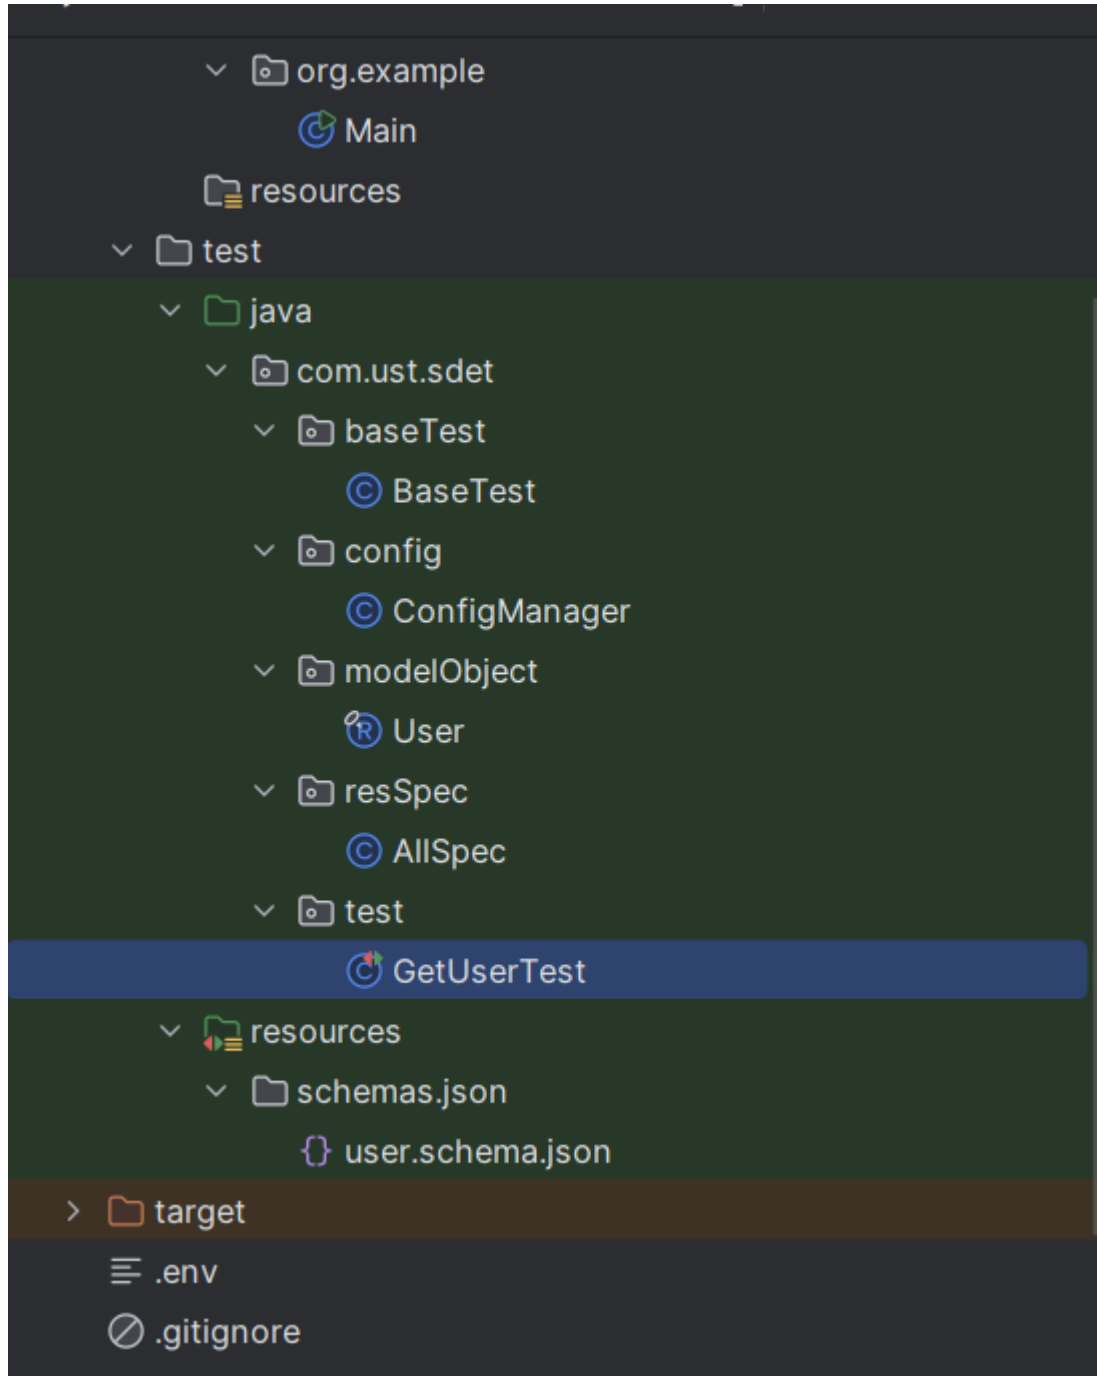

Objective

I have Wrote an API automation framework for the <https://jsonplaceholder.typicode.com> using Rest Assured and JUnit 5. The main purpose of this framework is to retrieve posts for a specific user and validate the response, by performing different CRUD operation such as Get.

Project Structure

The project is divided into different packages to keep the code clean and easy to maintain.

Folder Structure

Technology Stack

The following technologies I have used for implementation:

Technology Purpose

Java Programming Language

Rest Assured API Automation

JUnit 5 Test Execution

Maven Build Management

Git Version Control

basetest

This package contains the BaseTest class. The base URL is initialized here so that it can be used across all test classes.

And I have wrote in that base Test Request Builder so that I don't need to pass manually every time.

config

The ConfigManager class stores the application URL, which is coming from .env file

.ENV

Base URL: <https://jsonplaceholder.typicode.com>

ModelObject

This package contains the request payload classes.

- User

I have used Java records to create these objects. So that no need to write getters and setters.

spec

The AllSpec class contains common response validations such as:

- Success response (200)

This avoids writing the same validations in every test.

test

This package contains all the API test classes.

- GetUserTest
- UserTest

resources

This folder contains JSON schema files used for schema validation.

Flow

1. Send a GET request to: **/posts?userId=1**
2. Validate:
 - a. Status Code = 200
 - b. Response is not empty
 - c. Every post has:
 - a. userId = 1

Expectations

1. Query Parameters
2. JSON Path
3. Loop through response
4. Assertions

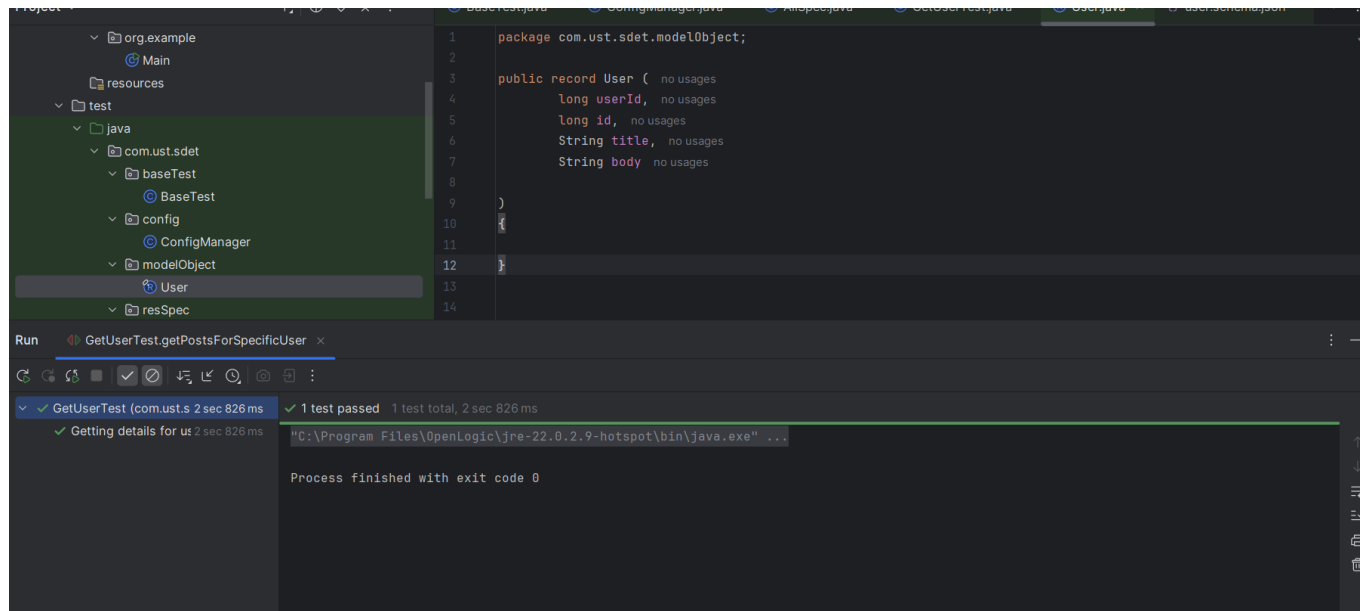

In this test I have covered:

- Send the Get req in order to fetch userID Details
- Am fetching specific userID=1

For userID APIs, the flow followed is:

Get → get userid → loop specific userID

And here am validating the status code is 200 and response is not empty and assertions

Schema Validation

Schema validation is implemented for the GET APIs.

The following schema is used:

- user.schema.json

Conclusion

This framework the fetching specific userID details and schema validation scenarios. The code is organized in separate packages, which makes it easy to maintain.
